Bum Simulator is an open-ended and humorous test system that permits players a look into the life of a vagrant. The amusement was developed by a team of indie gamers with a background in. In an air conditioner described in JP-A-8-241381, there is provided a tube storing means which rotatably holds an air conditioning tube (air duct) so as to change the direction of the tube. In the air conditioner, an air channel forming plate is fixed to an outer peripheral part of the tube storing means, and a fan, a heat exchanger, an air blowing-out port, and a partitioning wall are arranged along the air channel in this order. In this air conditioner, a distance between a heat exchanger and an air blowing-out port is set to be larger than a height of the partitioning wall from a floor surface. A step portion is formed at a leading end part of the partitioning wall, and an upper portion of the partitioning wall is disposed to have a shape of being raised in a vertically direction. This step portion is formed so as to reduce the height of the partitioning wall with respect to the heat exchanger. In the air conditioner, a step height of the step portion is set to be smaller than the height of the air blowing-out port. Therefore, a distance between a heat exchanger and an air blowing-out port can be reduced by a distance, which is equal to the height of the step portion of the partitioning wall, to suppress a reduction in the size of the air blowing-out port. Thus, it is possible to suppress the reduction in the flow amount of air blown out through the air blowing-out port, which can cause a reduction in cooling performance. However, in the air conditioner described in JP-A-8-241381, the air channel forming plate is formed of a flexible material so as to change the direction of the air conditioning tube. Therefore, when the air channel forming plate is rotated, the air conditioning tube, which is rot
