To evaluate the long-term efficacy of a standardized laparoscopic Nissen fundoplication for gastroesophageal reflux disease. Prospective clinical study. University Hospital, Ghent, Belgium. Forty-seven consecutive patients with gastroesophageal reflux disease were operated on from February 1995 to December 1998. Forty-seven patients, with a mean age of 46 years (range, 21-70 years) and with a mean weight of 86 kg (range, 50-135 kg), were prospectively included in a follow-up program until June 2002. The operating time, postoperative complications, perioperative and long-term complications, and the need for surgery at a later stage were recorded. The evaluation of the clinical outcome included the use of a standardized questionnaire in a telephone interview. Preoperative data revealed moderate-to-severe symptoms in 32 patients (68%), mild symptoms in 11 patients (23%), and normalization of symptoms in four patients (9%). Reflux index in ambulatory 24-hour esophageal pH monitoring ranged from 10% to 30%. Preoperative parameters were not predictive of the postoperative long-term outcome. The most important postoperative complication was a pneumothorax that
